

Chapter 6

Data Types

Chapter 6 Topics

- Introduction
- Primitive Data Types
- Character String Types
- User-Defined Ordinal Types
- Array Types
- Associative Arrays
- Record Types
- Tuple Types
- List Types
- Union Types
- Pointer and Reference Types
- Type Checking
- Strong Typing
- Type Equivalence
- Theory and Data Types

Copyright © 2012 Addison-Wesley. All rights reserved.

1-2

6.1 Introduction

- A **data type** defines a collection of data objects and a set of predefined operations on those objects
- A **descriptor** is the collection of the attributes of a variable *used for type checking*
- An **object** represents an instance of a user-defined (abstract data) type
- One design issue for all data types: What operations are defined and how are they specified?

Copyright © 2012 Addison-Wesley. All rights reserved.

1-3

6.2 Primitive Data Types

- Almost all programming languages provide a set of **primitive data types**
- **Primitive data types**: Those not defined in terms of other data types
- Some primitive data types are merely reflections of the hardware
- Others require only a little non-hardware support for their implementation

Copyright © 2012 Addison-Wesley. All rights reserved.

1-4

Primitive Data Types: Integer

- Almost always an exact reflection of the hardware so the mapping is trivial
- There may be as many as eight different integer types in a language
- Java's signed integer sizes: `byte`, `short`, `int`, `long`

*integers are stored as a string of bits
↑
0's and 1's*

Copyright © 2012 Addison-Wesley. All rights reserved.

1-5

Primitive Data Types: Floating Point

- Model real numbers, but only as approximations *.01 is finite but in binary is ∞*
- Languages for scientific use support at least two floating-point types (e.g., `float` and `double`; sometimes more)
- Usually exactly like the hardware, but not always
- IEEE Floating-Point Standard 754

Copyright © 2012 Addison-Wesley. All rights reserved.

1-6

floating point values are stored in something similar to scientific notation: $a \times 10^b$

since stored as binary $\rightarrow a \times 2^b$

Issues w/ Floating Pt. Numbers

- 1) precision - accuracy of the fractional part of a value (in bits or decimal places)
- 2) range - combination of the range of the fractional part and of exponents allowed

Primitive Data Types: Complex ^{atbi}

- Some languages support a complex type, e.g., C99, Fortran, and Python
- Each value consists of two floats, the real part and the imaginary part
- Literal form (in Python):
(7 + 3j), where 7 is the real part and 3 is the imaginary part

(a, b)

Copyright © 2012 Addison-Wesley. All rights reserved.

1.7

Primitive Data Types: Decimal

- For business applications (money)
 - Essential to COBOL
 - C# offers a decimal data type
- Store a fixed number of decimal digits, in coded form (BCD)
- *Advantage*: accuracy
- *Disadvantages*: limited range, wastes memory

e.g. a 6 digit coded decimal # requires 24 bits of memory but only 20 bits if stored as a binary number

Copyright © 2012 Addison-Wesley. All rights reserved.

1.8

Primitive Data Types: Boolean

- Simplest of all
- Range of values: two elements, one for "true" and one for "false"
- Could be implemented as bits, but often as bytes
 - Advantage: readability

Copyright © 2012 Addison-Wesley. All rights reserved.

1.9

Primitive Data Types: Character

- Stored as numeric codings ^{usually a single character only}
- Most commonly used coding: ASCII
- An alternative, 16-bit coding: Unicode (UCS-2)
 - Includes characters from most natural languages
 - Originally used in Java
 - C# and JavaScript also support Unicode
- 32-bit Unicode (UCS-4)
 - Supported by Fortran, starting with 2003

Copyright © 2012 Addison-Wesley. All rights reserved.

1.10

6.3 Character String Types

- Values are sequences of characters
- Design issues:
 - Is it a primitive type or just a special kind of array?
 - Should the length of strings be static or dynamic?

string variables
string constants – "The sum is:"

Copyright © 2012 Addison-Wesley. All rights reserved.

5-11

Character String Types Operations

- Typical operations:
 - Assignment and copying
 - Comparison (=, >, etc.)
 - Catenation
 - Substring reference
 - Pattern matching

Michele Starkey
subsetting

Copyright © 2012 Addison-Wesley. All rights reserved.

5-12

Character String Type in Certain Languages

- C and C++
 - Not primitive
 - Use `char` arrays and a library of functions that provide operations
- SNOBOL4 (a string manipulation language)
 - Primitive
 - Many operations, including elaborate pattern matching
- Fortran and Python
 - Primitive type with assignment and several operations
- Java
 - Primitive via the `String` class
- Perl, JavaScript, Ruby, and PHP
 - Provide built-in pattern matching, using regular expressions

Copyright © 2012 Addison-Wesley. All rights reserved.

5-13

Character String Length Options

- Static: COBOL, Java's `String` class
- *Limited Dynamic Length*: C and C++
 - In these languages, a special character is used to indicate the end of a string's characters, rather than maintaining the length
- *Dynamic* (no maximum): SNOBOL4, Perl, JavaScript
- Ada supports all three string length options

Copyright © 2012 Addison-Wesley. All rights reserved.

5-14

Character String Type Evaluation

- Aid to writability
- As a primitive type with static length, they are inexpensive to provide—why not have them?
- Dynamic length is nice, but is it worth the expense?

Copyright © 2012 Addison-Wesley. All rights reserved.

5-15

Character String Implementation

- Static length: compile-time descriptor
- Limited dynamic length: may need a run-time descriptor for length (but not in C and C++)
- Dynamic length: need run-time descriptor; allocation/deallocation is the biggest implementation problem

Copyright © 2012 Addison-Wesley. All rights reserved.

5-16

Compile- and Run-Time Descriptors

Static string

5-17

6.4 User-Defined Ordinal Types

- An **ordinal type** is one in which the range of possible values can be easily associated with the set of positive integers
- Examples of primitive ordinal types in Java
 - integer
 - char
 - boolean

2 Types of Ordinal Types

Copyright © 2012 Addison-Wesley. All rights reserved.

1-18

① Enumeration Types

- All possible values, which are named constants, are provided in the definition
- C# example

```
enum days {mon, tue, wed, thu, fri, sat, sun};
```
- Design issues
 - Is an enumeration constant allowed to appear in more than one type definition, and if so, how is the type of an occurrence of that constant checked?
 - Are enumeration values coerced to integer?
 - Any other type coerced to an enumeration type?

Copyright © 2012 Addison-Wesley. All rights reserved.

1-19

Evaluation of Enumerated Type

- Aid to readability, e.g., no need to code a color as a number
- Aid to reliability, e.g., compiler can check:
 - operations (don't allow colors to be added)
 - No enumeration variable can be assigned a value outside its defined range
 - Ada, C#, and Java 5.0 provide better support for enumeration than C++ because enumeration type variables in these languages are not coerced into integer types

Copyright © 2012 Addison-Wesley. All rights reserved.

1-20

② Subrange Types

- An ordered contiguous subsequence of an ordinal type
 - Example: 12..18 is a subrange of integer type
- Ada's design

```
type Days is (mon, tue, wed, thu, fri, sat, sun);
subtype Weekdays is Days range mon..fri;
subtype Index is Integer range 1..100;

Day1: Days;
Day2: Weekday;
Day2 := Day1;
```

Copyright © 2012 Addison-Wesley. All rights reserved.

1-21

Subrange Evaluation

- Aid to readability
 - Make it clear to the readers that variables of subrange can store only certain range of values
- Reliability
 - Assigning a value to a subrange variable that is outside the specified range is detected as an error

Copyright © 2012 Addison-Wesley. All rights reserved.

1-22

Implementation of User-Defined Ordinal Types

- Enumeration types are implemented as integers
- Subrange types are implemented like the parent types with code inserted (by the compiler) to restrict assignments to subrange variables

Copyright © 2012 Addison-Wesley. All rights reserved.

1.23

6.5 Array Types

- An array is a homogeneous aggregate of data elements in which an individual element is identified by its position in the aggregate, relative to the first element.

Copyright © 2012 Addison-Wesley. All rights reserved.

1.24

Array Design Issues

- What types are legal for subscripts?
- Are subscripting expressions in element references range checked?
- When are subscript ranges bound?
- When does allocation take place?
- Are ragged or rectangular multidimensional arrays allowed, or both?
- What is the maximum number of subscripts?
- Can array objects be initialized?
- Are any kind of slices supported?

Copyright © 2012 Addison-Wesley. All rights reserved.

1.25

Array Indexing

- *Indexing* (or subscripting) is a mapping from indices to elements
`array_name (index_value_list) → an element`
- Index Syntax
 - Fortran and Ada use parentheses
 - Ada explicitly uses parentheses to show uniformity between array references and function calls because both are *mappings*
 - Most other languages use brackets

Copyright © 2012 Addison-Wesley. All rights reserved.

1.26

Arrays Index (Subscript) Types

- FORTRAN, C: integer only
- Ada: integer or enumeration (includes Boolean and char)
- Java: integer types only
- Index range checking
 - C, C++, Perl, and Fortran do not specify range checking
 - Java, ML, C# specify range checking
 - In Ada, the default is to require range checking, but it can be turned off

Copyright © 2012 Addison-Wesley. All rights reserved.

1.27

Subscript Binding and Array Categories

- *Static*: subscript ranges are statically bound and storage allocation is static (before run-time)
 - Advantage: efficiency (no dynamic allocation)
- *Fixed stack-dynamic*: subscript ranges are statically bound, but the allocation is done at declaration time
 - Advantage: space efficiency

Copyright © 2012 Addison-Wesley. All rights reserved.

1.28

Subscript Binding and Array Categories (continued)

- *Stack-dynamic*: subscript ranges are dynamically bound and the storage allocation is dynamic (done at run-time)
 - Advantage: flexibility (the size of an array need not be known until the array is to be used)
- *Fixed heap-dynamic*: similar to fixed stack-dynamic: storage binding is dynamic but fixed after allocation (i.e., binding is done when requested and storage is allocated from heap, not stack)

Copyright © 2012 Addison-Wesley. All rights reserved.

1-29

Subscript Binding and Array Categories (continued)

- *Heap-dynamic*: binding of subscript ranges and storage allocation is dynamic and can change any number of times
 - Advantage: flexibility (arrays can grow or shrink during program execution)

Copyright © 2012 Addison-Wesley. All rights reserved.

1-30

Subscript Binding and Array Categories (continued)

- C and C++ arrays that include `static` modifier are static
- C and C++ arrays without `static` modifier are fixed stack-dynamic
- C and C++ provide fixed heap-dynamic arrays
- C# includes a second array class `ArrayList` that provides fixed heap-dynamic
- Perl, JavaScript, Python, and Ruby support heap-dynamic arrays

Copyright © 2012 Addison-Wesley. All rights reserved.

1-31

Array Initialization

- Some language allow initialization at the time of storage allocation
 - C, C++, Java, C# example
- ```
int list [] = {4, 5, 7, 83}
char name [] = "freddie";
char *names [] = {"Bob", "Jake", "Joe"};
String[] names = {"Bob", "Jake", "Joe"};
```

Copyright © 2012 Addison-Wesley. All rights reserved.

1-32

## Heterogeneous Arrays

- A *heterogeneous array* is one in which the elements need not be of the same type
- Supported by Perl, Python, JavaScript, and Ruby

Copyright © 2012 Addison-Wesley. All rights reserved.

1-33

## Array Initialization

- C-based languages
  - `int list [] = {1, 3, 5, 7}`
  - `char *names [] = {"Mike", "Fred", "Mary Lou"};`
- Ada
  - `List : array (1..5) of Integer := (1 => 17, 3 => 34, others => 0);`
- Python
  - List comprehensions

```
list = [x ** 2 for x in range(12) if x % 3 == 0]
puts [0, 9, 36, 81] in list
```

Copyright © 2012 Addison-Wesley. All rights reserved.

1-34

## Arrays Operations

- APL provides the most powerful array processing operations for vectors and matrixes as well as unary operators (for example, to reverse column elements)
- Ada allows array assignment but also catenation
- Python's array assignments, but they are only reference changes. Python also supports array catenation and element membership operations
- Ruby also provides array catenation
- Fortran provides *elemental* operations because they are between pairs of array elements
  - For example, + operator between two arrays results in an array of the sums of the element pairs of the two arrays

Copyright © 2012 Addison-Wesley. All rights reserved.

1-35

## Rectangular and Jagged Arrays

- A rectangular array is a multi-dimensional array in which all of the rows have the same number of elements and all columns have the same number of elements
- A jagged matrix has rows with varying number of elements
  - Possible when multi-dimensional arrays actually appear as arrays of arrays
- C, C++, and Java support jagged arrays
- Fortran, Ada, and C# support rectangular arrays (C# also supports jagged arrays)

Copyright © 2012 Addison-Wesley. All rights reserved.

1-36

## Slices

- A slice is some substructure of an array; nothing more than a referencing mechanism
- Slices are only useful in languages that have array operations

Copyright © 2012 Addison-Wesley. All rights reserved.

1-37

## Slice Examples

- Python
 

```
vector = [2, 4, 6, 8, 10, 12, 14, 16]
mat = [[1, 2, 3], [4, 5, 6], [7, 8, 9]]
```

`vector[3:6]` is a three-element array  
`mat[0][0:2]` is the first and second element of the first row of `mat`
- Ruby supports slices with the `slice` method
 

```
list.slice(2, 2) returns the third and fourth elements of list
```

Copyright © 2012 Addison-Wesley. All rights reserved.

1-38

## Implementation of Arrays

- Access function maps subscript expressions to an address in the array
- Access function for single-dimensional arrays:
 
$$\text{address}(\text{list}[k]) = \text{address}(\text{list}[\text{lower\_bound}]) + ((k - \text{lower\_bound}) * \text{element\_size})$$

Copyright © 2012 Addison-Wesley. All rights reserved.

1-39

## Accessing Multi-dimensional Arrays

- Two common ways:
  - Row major order (by rows) – used in most languages
  - Column major order (by columns) – used in Fortran
- A compile-time descriptor for a multidimensional array

|                        |
|------------------------|
| Multidimensional array |
| Element type           |
| Index type             |
| Number of dimensions   |
| Index range 0          |
| ⋮                      |
| Index range n - 1      |
| Address                |

Copyright © 2012 Addison-Wesley. All rights reserved.

1-40

## Locating an Element in a Multi-dimensional Array

- General format

Location  $a[i,j]$  = address of  $a[\text{row\_lb}, \text{col\_lb}] + (((i - \text{row\_lb}) * n) + (j - \text{col\_lb})) * \text{element\_size}$

Copyright © 2012 Addison-Wesley. All rights reserved.

1-48

## Compile-Time Descriptors

| Array             |
|-------------------|
| Element type      |
| Index type        |
| Index lower bound |
| Index upper bound |
| Address           |

Single-dimensional array

| Multidimensional array |
|------------------------|
| Element type           |
| Index type             |
| Number of dimensions   |
| Index range 1          |
| ⋮                      |
| Index range n          |
| Address                |

Multidimensional array

Copyright © 2012 Addison-Wesley. All rights reserved.

1-49

## 6.6 Associative Arrays

- An *associative array* is an unordered collection of data elements that are indexed by an equal number of values called *keys*
  - User-defined keys must be stored
- Design issues:
  - What is the form of references to elements?
  - Is the size static or dynamic?
- Built-in type in Perl, Python, Ruby, and Lua
  - In Lua, they are supported by tables

Copyright © 2012 Addison-Wesley. All rights reserved.

1-50

## Associative Arrays in Perl

- Names begin with `%`; literals are delimited by parentheses
 

```
%hi_temps = ("Mon" => 77, "Tue" => 79, "Wed" => 65, ...);
```
- Subscripting is done using braces and keys
 

```
$hi_temps{"Wed"} = 83;
```

  - Elements can be removed with `delete`

```
delete $hi_temps{"Tue"};
```

Copyright © 2012 Addison-Wesley. All rights reserved.

1-51

## 6.7 Record Types

- A *record* is a possibly heterogeneous aggregate of data elements in which the individual elements are identified by names
- Design issues:
  - What is the syntactic form of references to the field?
  - Are elliptical references allowed

Copyright © 2012 Addison-Wesley. All rights reserved.

1-52

## Definition of Records in COBOL

- COBOL uses level numbers to show nested records; others use recursive definition

```
01 EMP-REC.
 02 EMP-NAME.
 05 FIRST PIC X(20).
 05 MID PIC X(10).
 05 LAST PIC X(20).
 02 HOURLY-RATE PIC 99V99.
```

Copyright © 2012 Addison-Wesley. All rights reserved.

1-53

## Definition of Records in Ada

- Record structures are indicated in an orthogonal way

```
type Emp_Rec_Type is record
 First: String (1..20);
 Mid: String (1..10);
 Last: String (1..20);
 Hourly_Rate: Float;
end record;
Emp_Rec: Emp_Rec_Type;
```

Copyright © 2012 Addison-Wesley. All rights reserved.

1-47

## References to Records

- Record field references
  - COBOL  
field\_name OF record\_name\_1 OF ... OF record\_name\_n
  - Others (dot notation)  
record\_name\_1.record\_name\_2. ... record\_name\_n.field\_name
- Fully qualified references must include all record names
- Elliptical references allow leaving out record names as long as the reference is unambiguous, for example in COBOL  
FIRST, FIRST OF EMP-NAME, and FIRST OF EMP-REC are elliptical references to the employee's first name

Copyright © 2012 Addison-Wesley. All rights reserved.

1-48

## Operations on Records

- Assignment is very common if the types are identical
- Ada allows record comparison
- Ada records can be initialized with aggregate literals
- COBOL provides MOVE CORRESPONDING
  - Copies a field of the source record to the corresponding field in the target record

Copyright © 2012 Addison-Wesley. All rights reserved.

1-49

## Evaluation and Comparison to Arrays

- Records are used when collection of data values is heterogeneous
- Access to array elements is much slower than access to record fields, because subscripts are dynamic (field names are static)
- Dynamic subscripts could be used with record field access, but it would disallow type checking and it would be much slower

Copyright © 2012 Addison-Wesley. All rights reserved.

1-50

## Implementation of Record Type

Offset address relative to the beginning of the records is associated with each field

Copyright © 2012 Addison-Wesley. All rights reserved.

1-51

## 6.8 Tuple Types

- A tuple is a data type that is similar to a record, except that the elements are not named
- Used in Python, ML, and F# to allow functions to return multiple values
  - Python
    - Closely related to its lists, but immutable
    - Create with a tuple literal  
myTuple = (3, 5.8, 'apple')
    - Referenced with subscripts (begin at 1)
    - Catenation with + and deleted with del

Copyright © 2012 Addison-Wesley. All rights reserved.

1-52

## Tuple Types (continued)

- ML

```
val myTuple = (3, 5.8, 'apple');
```

- Access as follows:

#1(myTuple) is the first element

- A new tuple type can be defined

```
type intReal = int * real;
```

- F#

```
let tup = (3, 5, 7)
```

```
let a, b, c = tup This assigns a tuple to
a tuple pattern (a, b, c)
```

Copyright © 2012 Addison-Wesley. All rights reserved.

1.63

## 6.9 List Types

- Lists in LISP and Scheme are delimited by parentheses and use no commas

(A B C D) and (A (B C) D)

- Data and code have the same form

As data, (A B C) is literally what it is

As code, (A B C) is the function A applied to the parameters B and C

- The interpreter needs to know which a list is, so if it is data, we quote it with an apostrophe

'(A B C) is data

Copyright © 2012 Addison-Wesley. All rights reserved.

1.64

## List Types (continued)

- List Operations in Scheme

- CAR returns the first element of its list parameter

(CAR '(A B C)) returns A

- CDR returns the remainder of its list parameter after the first element has been removed

(CDR '(A B C)) returns (B C)

- CONS puts its first parameter into its second parameter, a list, to make a new list

(CONS 'A (B C)) returns (A B C)

- LIST returns a new list of its parameters

(LIST 'A 'B '(C D)) returns (A B (C D))

Copyright © 2012 Addison-Wesley. All rights reserved.

1.66

## List Types (continued)

- List Operations in ML

- Lists are written in brackets and the elements are separated by commas

- List elements must be of the same type

- The Scheme CONS function is a binary operator in ML, ::

3 :: [5, 7, 9] evaluates to [3, 5, 7, 9]

- The Scheme CAR and CDR functions are named hd and tl, respectively

Copyright © 2012 Addison-Wesley. All rights reserved.

1.66

## List Types (continued)

- F# Lists

- Like those of ML, except elements are separated by semicolons and hd and tl are methods of the List class

- Python Lists

- The list data type also serves as Python's arrays

- Unlike Scheme, Common LISP, ML, and F#, Python's lists are mutable

- Elements can be of any type

- Create a list with an assignment

```
myList = [3, 5.8, "grape"]
```

Copyright © 2012 Addison-Wesley. All rights reserved.

1.67

## List Types (continued)

- Python Lists (continued)

- List elements are referenced with subscripting, with indices beginning at zero

```
x = myList[1] Sets x to 5.8
```

- List elements can be deleted with del

```
del myList[1]
```

- List Comprehensions - derived from set notation

```
[x * x for x in range(6) if x % 3 == 0]
```

```
range(12) creates [0, 1, 2, 3, 4, 5, 6]
```

Constructed list: [0, 9, 36]

Copyright © 2012 Addison-Wesley. All rights reserved.

1.68

## List Types (continued)

- Haskell's List Comprehensions
  - The original
 

```
[n * n | n <- [1..10]]
```
- F#'s List Comprehensions
 

```
let myArray = [|for i in 1..5 -> [i * i] |]
```
- Both C# and Java supports lists through their generic heap-dynamic collection classes, `List` and `ArrayList`, respectively

Copyright © 2012 Addison-Wesley. All rights reserved.

1.60

## 6.10 Unions Types

- A *union* is a type whose variables are allowed to store different type values at different times during execution
- Design issues
  - Should type checking be required?
  - Should unions be embedded in records?

Copyright © 2012 Addison-Wesley. All rights reserved.

1.60

## Discriminated vs. Free Unions

- Fortran, C, and C++ provide union constructs in which there is no language support for type checking; the union in these languages is called *free union*
- Type checking of unions require that each union include a type indicator called a *discriminant*
  - Supported by Ada

Copyright © 2012 Addison-Wesley. All rights reserved.

1.61

## Ada Union Types

```
type Shape is (Circle, Triangle, Rectangle);
type Colors is (Red, Green, Blue);
type Figure (Form: Shape) is record
 Filled: Boolean;
 Color: Colors;
 case Form is
 when Circle => Diameter: Float;
 when Triangle =>
 Leftside, Rightside: Integer;
 Angle: Float;
 when Rectangle => Side1, Side2: Integer;
 end case;
end record;
```

Copyright © 2012 Addison-Wesley. All rights reserved.

1.62

## Ada Union Type Illustrated

A discriminated union of three shape variables

Copyright © 2012 Addison-Wesley. All rights reserved.

1.63

## Implementation of Unions

```
type Node (Tag : Boolean) is
 record
 case Tag is
 when True => Count : Integer;
 when False => Sum : Float;
 end case;
 end record;
```

Copyright © 2012 Addison-Wesley. All rights reserved.

1.64

## Evaluation of Unions

- Free unions are unsafe
  - Do not allow type checking
- Java and C# do not support unions
  - Reflective of growing concerns for safety in programming language
- Ada's discriminated unions are safe

Copyright © 2012 Addison-Wesley. All rights reserved.

1.66

## 6.11 Pointer and Reference Types

- A *pointer* type variable has a range of values that consists of memory addresses and a special value, *nil*
- Provide the power of indirect addressing
- Provide a way to manage dynamic memory
- A pointer can be used to access a location in the area where storage is dynamically created (usually called a *heap*)

Copyright © 2012 Addison-Wesley. All rights reserved.

1.66

## Design Issues of Pointers

- What are the scope of and lifetime of a pointer variable?
- What is the lifetime of a heap-dynamic variable?
- Are pointers restricted as to the type of value to which they can point?
- Are pointers used for dynamic storage management, indirect addressing, or both?
- Should the language support pointer types, reference types, or both?

Copyright © 2012 Addison-Wesley. All rights reserved.

1.67

## Pointer Operations

- Two fundamental operations: assignment and dereferencing
- Assignment is used to set a pointer variable's value to some useful address
- Dereferencing yields the value stored at the location represented by the pointer's value
  - Dereferencing can be explicit or implicit
  - C++ uses an explicit operation via `*`
    - `j = *ptr`  
sets `j` to the value located at `ptr`

Copyright © 2012 Addison-Wesley. All rights reserved.

1.68

## Pointer Assignment Illustrated

The assignment operation `j = *ptr`

Copyright © 2012 Addison-Wesley. All rights reserved.

1.68

## Problems with Pointers

- Dangling pointers (dangerous)
  - A pointer points to a heap-dynamic variable that has been deallocated
- Lost heap-dynamic variable
  - An allocated heap-dynamic variable that is no longer accessible to the user program (often called *garbage*)
    - Pointer `p1` is set to point to a newly created heap-dynamic variable
    - Pointer `p1` is later set to point to another newly created heap-dynamic variable
    - The process of losing heap-dynamic variables is called *memory leakage*

Copyright © 2012 Addison-Wesley. All rights reserved.

1.70

## Pointers in Ada

- Some dangling pointers are disallowed because dynamic objects can be automatically deallocated at the end of pointer's type scope
- The lost heap-dynamic variable problem is not eliminated by Ada (possible with `UNCHECKED_DEALLOCATION`)

1.71

## Pointers in C and C++

- Extremely flexible but must be used with care
- Pointers can point at any variable regardless of when or where it was allocated
- Used for dynamic storage management and addressing
- Pointer arithmetic is possible
- Explicit dereferencing and address-of operators
- Domain type need not be fixed (`void *`)
  - `void *` can point to any type and can be type checked (cannot be de-referenced)

1.72

## Pointer Arithmetic in C and C++

```
float stuff[100];
float *p;
p = stuff;
```

`*(p+5)` is equivalent to `stuff[5]` and `p[5]`  
`*(p+i)` is equivalent to `stuff[i]` and `p[i]`

1.73

## Reference Types

- C++ includes a special kind of pointer type called a *reference type* that is used primarily for formal parameters
  - Advantages of both pass-by-reference and pass-by-value
- Java extends C++'s reference variables and allows them to replace pointers entirely
  - References are references to objects, rather than being addresses
- C# includes both the references of Java and the pointers of C++

1.74

## Evaluation of Pointers

- Dangling pointers and dangling objects are problems as is heap management
- Pointers are like `goto`'s--they widen the range of cells that can be accessed by a variable
- Pointers or references are necessary for dynamic data structures--so we can't design a language without them

Copyright © 2012 Addison-Wesley. All rights reserved.

1.76

## Representations of Pointers

- Large computers use single values
- Intel microprocessors use segment and offset

Copyright © 2012 Addison-Wesley. All rights reserved.

1.76

## Dangling Pointer Problem

- **Tombstone:** extra heap cell that is a pointer to the heap-dynamic variable
  - The actual pointer variable points only at tombstones
  - When heap-dynamic variable de-allocated, tombstone remains but set to nil
  - Costly in time and space
- **Locks-and-keys:** Pointer values are represented as (key, address) pairs
  - Heap-dynamic variables are represented as variable plus cell for integer lock value
  - When heap-dynamic variable allocated, lock value is created and placed in lock cell and key cell of pointer

1.77

## Heap Management

- A very complex run-time process
- Single-size cells vs. variable-size cells
- Two approaches to reclaim garbage
  - Reference counters (*eager approach*): reclamation is gradual
  - Mark-sweep (*lazy approach*): reclamation occurs when the list of variable space becomes empty

Copyright © 2012 Addison-Wesley. All rights reserved.

1.78

## Reference Counter

- **Reference counters:** maintain a counter in every cell that store the number of pointers currently pointing at the cell
  - **Disadvantages:** space required, execution time required, complications for cells connected circularly
  - **Advantage:** it is intrinsically incremental, so significant delays in the application execution are avoided

1.79

## Mark-Sweep

- The run-time system allocates storage cells as requested and disconnects pointers from cells as necessary; mark-sweep then begins
  - Every heap cell has an extra bit used by collection algorithm
  - All cells initially set to garbage
  - All pointers traced into heap, and reachable cells marked as not garbage
  - All garbage cells returned to list of available cells
  - Disadvantages: in its original form, it was done too infrequently. When done, it caused significant delays in application execution. Contemporary mark-sweep algorithms avoid this by doing it more often—called incremental mark-sweep

## Marking Algorithm

Copyright © 2012 Addison-Wesley. All rights reserved.

1.81

## Variable-Size Cells

- All the difficulties of single-size cells plus more
- Required by most programming languages
- If mark-sweep is used, additional problems occur
  - The initial setting of the indicators of all cells in the heap is difficult
  - The marking process is nontrivial
  - Maintaining the list of available space is another source of overhead

## 6.12 Type Checking

- Generalize the concept of operands and operators to include subprograms and assignments
- *Type checking* is the activity of ensuring that the operands of an operator are of compatible types
- A *compatible type* is one that is either legal for the operator, or is allowed under language rules to be implicitly converted, by compiler-generated code, to a legal type
  - This automatic conversion is called a *coercion*.
- A *type error* is the application of an operator to an operand of an inappropriate type

1.83

## Type Checking (continued)

- If all type bindings are static, nearly all type checking can be static
- If type bindings are dynamic, type checking must be dynamic
- A programming language is *strongly typed* if type errors are always detected
- **Advantage of strong typing:** allows the detection of the misuses of variables that result in type errors

Copyright © 2012 Addison-Wesley. All rights reserved.

1.84

## 6.13 Strong Typing

### Language examples:

- C and C++ are not: parameter type checking can be avoided; unions are not type checked
- Ada is, almost (UNCHECKED\_CONVERSION is loophole) (Java and C# are similar to Ada)

Copyright © 2012 Addison-Wesley. All rights reserved.

1.85

## Strong Typing (continued)

- Coercion rules strongly affect strong typing—they can weaken it considerably (C++ versus Ada)
- Although Java has just half the assignment coercions of C++, its strong typing is still far less effective than that of Ada

1.86

## 6.14 Name Type Equivalence

- *Name type equivalence* means the two variables have equivalent types if they are in either the same declaration or in declarations that use the same type name
- **Easy to implement but highly restrictive:**
  - Subranges of integer types are not equivalent with integer types
  - Formal parameters must be the same type as their corresponding actual parameters

Copyright © 2012 Addison-Wesley. All rights reserved.

1.87

## Structure Type Equivalence

- *Structure type equivalence* means that two variables have equivalent types if their types have identical structures
- More flexible, but harder to implement

Copyright © 2012 Addison-Wesley. All rights reserved.

1.88

## Type Equivalence (continued)

- Consider the problem of two structured types:
  - Are two record types equivalent if they are structurally the same but use different field names?
  - Are two array types equivalent if they are the same except that the subscripts are different? (e.g. [1..10] and [0..9])
  - Are two enumeration types equivalent if their components are spelled differently?
  - With structural type equivalence, you cannot differentiate between types of the same structure (e.g. different units of speed, both float)

1.80

## 6.15 Theory and Data Types

- Type theory is a broad area of study in mathematics, logic, computer science, and philosophy
- Two branches of type theory in computer science:
  - Practical – data types in commercial languages
  - Abstract – typed lambda calculus
- A type system is a set of types and the rules that govern their use in programs

Copyright © 2012 Addison-Wesley. All rights reserved.

1.80

## Theory and Data Types (continued)

- Formal model of a type system is a set of types and a collection of functions that define the type rules
  - Either an attribute grammar or a type map could be used for the functions
  - Finite mappings – model arrays and functions
  - Cartesian products – model tuples and records
  - Set unions – model union types
  - Subsets – model subtypes

1.81

## Summary

- The data types of a language are a large part of what determines that language's style and usefulness
- The primitive data types of most imperative languages include numeric, character, and Boolean types
- The user-defined enumeration and subrange types are convenient and add to the readability and reliability of programs
- Arrays and records are included in most languages
- Pointers are used for addressing flexibility and to control dynamic storage management
